

In the Specification:

Please replace the Abstract with the following amended Abstract:

a¹ An automated method of improving digital color images at high speed, which supports pipe-lining and has very little memory requirements, and is therefore specially suitable for on-the-fly processing of real time video, as well as for processing of large batches of images without the need of human intervention. The method includes a novel dynamic range adaptation scheme that operates on the norm of the image, which is suitable as is for ~~non-color~~ gray-scale images. For color images, a simple color reconstruction stage is added that maintains optimal color fidelity.

Please replace the paragraph beginning on page 4 line 2 with the following amended paragraph:

a² It is an object of the present invention to provide an automated method for real-time improvement of digital video, and for high speed improvement of large batches of digital images for both color and ~~non-color~~ gray-scale cases.

Please replace the paragraph beginning on page 5 line 10 with the following amended paragraph:

a³ Figure 3 is a schematic view of a way to carry out a second embodiment of the present invention where a ~~non-color~~ gray-scale image can be improved in terms of automatic self adaptation of both dynamic range and spatial resolution.

✓
Please replace the paragraph beginning on page 5 line 14 with the following amended paragraph:

a4
The present invention is of a method for automated high speed improvement of digital color images. Specifically, the method of the present invention can be used to support pipe-lining, and requires very little memory, hence being especially suitable for on-the-fly processing of real time video, as well as for processing of large batches of images without the need of human intervention. The method of the present invention includes a novel dynamic range compression process that operates on the Euclidean norm of the image, and is suitable as is for ~~non-color~~ gray-scale images. For color images, a simple color reconstruction stage is added, a stage that maintains optimal color fidelity.

✓
Please replace the paragraph beginning on page 6 line 1 with the following amended paragraph:

a5
Referring now to the drawings, and in particular to Fig. 1, a system 100 is shown to carry out a first embodiment of the method of the present invention. This embodiment is used by way of example to demonstrate the image improvement in terms of self adaptation of dynamic range and spatial resolution, as well as in terms of high fidelity color reconstruction, as they are related to color images. It is to be understood that the present method can be easily reduced to ~~non-color~~ gray-scale images, as further explained in detail below. System 100 consists of a digital image supplier 10 such as a camera, a DVD player, a hard disk, etc., that is capable of outputting a sequence of digital color images or frames. Each one of the frames is

a5
concl

represented by a set of matrices of similar size: $C_1(i,j)$, $C_2(i,j)$, ..., $C_n(i,j)$... $C_m(i,j)$, where $C_n(i,j)$ is the intensity value of the image in the n th color component, at the pixel whose coordinates on a display 16, e.g., a monitor or a printer, are row i and column j . In the case where said sequence of frames is part of a video movie, it is a common practice to supply each frame as a time sequence of pixels data, going first over the first row starting with its first column and ending with its last column, then repeating this process for the second row, etc., until the last column of the last row is reached.

Please replace the paragraph beginning on page 6 line 28 with the following amended paragraph:

a^b

It is readily seen from Eqn. (1) that for a ~~non-color~~ gray-scale image, i.e., when $m=1$, and the source image is simply $C_1(i,j) \equiv C(i,j)$, Eqn. (1) is reduced to $N(i,j) \equiv C(i,j)$, i.e. the norm of a ~~non-color~~ gray-scale image is the image itself. The DRC process according to Fig. 1 is further advanced by feeding the norm $N(i,j)$ into a Light DRC processor 12 and a Dark DRC processor 13.

Please replace the paragraph beginning on page 7 line 6 with the following amended paragraph:

a⁷

However, the norm of a color image is in itself a ~~non-color~~ gray-scale image, so that except for a color filter 15 in Fig. 1, the rest of the DRC process for a color image, represented by blocks 12, 13 and a balance filter 14, is identical with the process for a ~~non-color~~ gray-scale image, as described in detail in the following.

Please replace Equation 3 with the following amended Equation:

a⁸

$$I_{neg}(i,j) = FS1 - \frac{FS - N(i,j)}{K + W * \{FS - N(i,j)\}} = FS1 - \frac{FS - N(i,j)}{K + FS - W * N(i,j)}$$

Please replace the paragraph beginning on page 10 line 6 with the following amended paragraph:

a⁹

$I_{neg}(i,j)$ is thus obtained by operating with the basic DRC filter of Eq. 2 on the so-called "negative", which is a non-negative mirror of the norm image: $FS - N(i,j)$ of the norm with respect to the line $N(i,j) = FS/2$, then taking the negative mirror image of the DRC result by subtracting it from FS with respect to half unity. This causes the graph of the average of the dark DRC image versus the average of the source image to look as a double-mirror image of the Weber's Law graph of Figure 2, once with respect to the line $Av\{I_i\} = FS/2$ and again with respect to the line $Av\{I_o\} = 1/2$, thereby causing the compression to operate mainly in the darker areas of the scenery, hence revealing more data in the lighter areas and complementing the light DRC image.

Please replace the paragraph beginning on page 12 line 3 with the following amended paragraph:

a¹⁰

Referring now to Fig. 3, a system 300 is shown to carry out a second embodiment of the present invention, which is related to ~~non-color~~ gray-scale images. This embodiment is obtained from the embodiment of Fig. 1 by way of reduction, where norm processor 11 and color filter 15 of Fig. 1 are both omitted. Then, for this ~~non-color~~ gray-scale embodiment, a ~~non-color~~ gray-scale image $C(i,j)$ is inputted

A10
corr¹¹
from a gray-scale Digital Image Supplier 30 directly into light and dark compressors 32 and 33, identical in way of operation and function with processors 12 and 13 respectively, of Fig. 1. The outputs of these processors are fed into a balance filter 34, whose function and operation is identical with that of filter 14 of Fig. 1. The ~~non-color~~ gray-scale image $I_{bal}(i,j)$ at the output of filter 34 is improved in terms of dynamic range and spatial resolution adaptation. This image is fed into a display 36 to be further displayed as a ~~non-color~~ gray-scale image.

✓
Please replace the paragraph beginning on page 12 line 14 with the following amended paragraph:

A11
Another preferred embodiment for color images is to apply a ~~non-color~~ gray-scale processor like system 300 of Fig. 3 to each one of the single color bands separately (e.g., to each one of the R, G, and B sequences of frames), and then feed the three dynamic range compressed outputs to a compatible (e.g., RGB) input of a display that ~~supports~~ supports this standard (e.g., a common VGA monitor). The advantage of this embodiment is a considerable saving in processing time, since the three DRC processors can operate simultaneously, while color filter 15 in Fig. 1, which is a large time resource consumer, is altogether removed in this embodiment.
